Abstract

We study the 't Hooft coupling g_t and the mass splitting of the ground-state baryons in a chiral quark model inspired by the large N_c QCD. Depending on g_t the Hartree wavefunction of light quark in baryons is used to map the mass hyperfine splittings for the octet and decuplet baryons. The 't Hooft coupling g_t that reproduces the data of baryon masses is determined to be around 1.57, which is small in the sense that $g_t^2/(4\pi N_c) \ll 1$.

1 Introduction

The 't Hooft's idea [1] that Quantum Chromodynamics (QCD) simplifies in the limit of large number of colors, N_c, had proven to be a valuable tool for exploring strong interaction[2, 3]. With the $1/N_c$ expansion of QCD, the qualitative explanations can be given for, for instance, the Okubo-Zweig-Iizuka rule, the Regge phenomenology, the soliton picture of baryon[2], the contracted $SU(2n_f)$ spin-flavor symmetry[4] of QCD, and the spin-flavor structure of many baryon properties[5, 6, 7, 8, 9]. The existences of the smooth limit of QCD at $N_c \to \infty$, with g^2N_c fixed(g is the QCD coupling

---

[*]Email:jiadj@nwnu.edu.cn

constant), has been studied and confirmed via lattice simulation of $SU(N_c)$ gauge theory[10, 11, 12] (see also [13] for a recent review).

It is hard, however, to say on theoretical grounds whether $1/N_c = 1/3$ can be considered small in real world where $N_c = 3$ without actually solving QCD for finite N_c. This is so because the answer depends crucially on how large are the coefficients companying with the expanding parameter $1/N_c$, the 't Hooft's coupling $g_t \equiv g^2 N_c$, which is assumed to be fixed to ensure the $SU(N_c)$ QCD(the one-loop gluon vacuum polarization, for instance) to have a smooth limit as N_c tends to infinity. As argued recently by Weinberg[14], the 't Hooft's coupling g_t may not be small at moderate energies such as the scale of m_ρ since the masses of the ρ mesons m_ρ is of order of Λ_{QCD} in the chiral limit. Combining the $1/N_c$ expansion of QCD with the early idea of the chiral theory [15, 16], Weinberg proposed a large-N_c chiral theory[14] of quarks, gluons, and pions which is effectively renormalizable to leading order of $1/N_c$. He suggests that such an effective field theory, with a small value of the 't Hooft coupling g_t at moderate energies, may explain why the naive quark model are so successful. It remains unknown how small g_t could be in the effective theory.

The purpose of this Letter is to estimate the value of the 't Hooft coupling g_t in the quark picture of baryons with pion included. We determine, in a large-N_c chiral quark model that is inspired by the Weinberg's large-N_c effective theory, the 't Hooft coupling by computing the mass splittings of the ground-state octet and decuplet baryons with the help of Witten's Hartree picture and mapping them to the data of baryon masses. The 't Hooft coupling g_t is found to be about $g_t \simeq 1.57$. This infer that when pion enters in the quark picture g_t can be considered small in the sense that $g_t^2/(4\pi N_c) \ll 1$.

The model we utilized here is a potential version of the large-N_c effective theory[14] where the gluon interaction is effectively described by the Hartree potentials with the form of the coulomb plus string potential. Conceptually, it resembles the (topological) chiral bag model [17] in the sense that the role of bag is played by the string-like confining potential, with the chiral symmetry implemented via the quark-pion interaction.

2 Confined quarks in baryon at large N_c

Inspired by the large-N_c QCD and the chiral theories[14], we use a large-N_c chiral model of baryon[15, 16] in which each of quark $q_i (i = 1, \cdots, N_c)$ in baryon moves in the confining Hartree potential of all $N_c - 1$ others, coupling with the pion in an invariant way under chiral symmetry. The model is

$$\begin{array}{c} \mathcal{L}^{Baryon} = \sum_{i=1}^{N_c} \bar{q}_i[i\gamma^\mu \partial_\mu - (m_q + S)U_5 - \gamma^0 V_G]q_i \\ +\mathcal{L}^\chi, \end{array} \tag{1}$$

where m_q is the effective mass of the light (up or down) quark q_i and (S, V_G, U_5) are the Hartree fields experienced by q_i, created by all other quarks in baryon. The scalar and vector interactions, S and V_G, stand for the effective QCD gluon interaction, which can be approximated by the string potential and the one-gluon-exchange(OGE) interaction, while

$$U_5 \equiv \exp(2i\gamma^5 \boldsymbol{T} \cdot \boldsymbol{\pi}/f_\pi),$$

is the chiral interaction that q_i is involved, with f_π the pion decay constant. The chiral dynamics $\mathcal{L}^\chi$ of the pion mesons $\boldsymbol{\pi}$ is chosen, for simplicity, be the Skyrme Lagrangian[18],

$$\mathcal{L}^\chi = \frac{f_\pi^2}{4} tr(\partial_\mu U \partial^\mu U^\dagger) + \frac{1}{32e_s^2} tr[\partial_\mu U U^\dagger, \partial_\nu U U^\dagger]^2, \tag{2}$$

with the chiral field $U = \exp(2i\boldsymbol{T} \cdot \boldsymbol{\pi}/f_\pi)$ being the nonlinear representation of the Goldstone bosons, $U^\dagger U = 1$. Here, f_π and the self-coupling $1/e_s$ of the chiral field scales like $\sqrt{N_c}$, while U(thereby U_5) $\sim \mathcal{O}(1)$ in the $1/N_c$ expansion. We note that the adding[19] of the term $\bar{q}U_5 q$ in (1) is used to restore chiral symmetry $q \to q e^{2i\gamma^5 \boldsymbol{T}\cdot\boldsymbol{\theta}}$ under which $U_5 \to e^{-2i\gamma^5 \boldsymbol{T}\cdot\boldsymbol{\theta}} U_5 e^{-2i\gamma^5 \boldsymbol{T}\cdot\boldsymbol{\theta}}$.

The model (1) is invariant under chiral symmetry and can be viewed, in a sense, as a potential version of the large-N_c effective theory[14] in that instead of using gluon interaction, we use the Hartree potentials S and V_G to effectively describe the flavor-independent part of the color confining interactions between the valence quarks in baryon, which are assumed to arise from the gluon interaction at long and short distance limit, respectively. For the explicit form of S and V_G in (1), we choose them to be of the string-like and one-gluon-exchange

$$S = \sigma_{string} r, V_G = f_c \alpha_s(r)/r, \tag{3}$$

with σ_{string} the string tension, $\alpha_s(r \gg 1) = g^2/4\pi \sim 1/N_c$. Here, $f_c = \frac{1}{2}(N_c - 1/N_c)$ is the color factor for the quark-antiquark interaction in its color singlet configuration. It comes from the formula

$$f_c = \frac{1}{4} tr\left(\frac{\lambda^\alpha}{\sqrt{N_c}} \frac{\lambda^\alpha}{\sqrt{N_c}}\right) = \frac{N_c^2 - 1}{2N_c}, \tag{4}$$

which becomes 4/3 when $N_c = 3$. Obviously, $f_c \alpha_s \sim 1 + \mathcal{O}(1/N_c^2)$ for large N_c.

For the string tension σ_{string} in (3), one known from the $SU(N_c)$ gauge theories on lattice[11] that $\sqrt{\sigma_{string}}/g_t = \mathcal{O}(1)$, up to a $1/N_c^2$ correction. Thus, the Hartree potentials (3) scale as $\mathcal{O}(1)$, being consistent with the argument in [2]. Note that $m_q \sim M^B/N_c \sim 1$ since the baryon mass grows linearly with N_c[2].

We describe our treatment of the strong coupling α_s in (3) as follows. With n_f quark flavors and the quark masses much less than the momentum transfer Q^2, the strong coupling α_s is running with Q, in lowest-order QCD, like

$$\alpha_s(Q^2) = \frac{12\pi}{(11N_c - 2n_f)\ln(Q^2/\Lambda_{QCD}^2)},$$

Since $\Lambda_{QCD} \simeq 250MeV$, $\alpha_s(Q^2)$ is small for $Q^2 > 1GeV^2$, but for any $N_c \geq 2$ the above perturbative formula diverges as $Q \to \Lambda_{QCD}$, which signals the onset of confinement. Since in the soft regime we are working we cannot avoid this divergence, we need to regularize $\alpha_s(Q^2)$, by assuming[20], for instance, that it saturates at some critical value $\alpha_{critical}(Q^2)$ as $Q \to 0$. In the work [20], the running behavior of $\alpha_s(Q^2)$ has the form of $\sum_{k=1}^{3} \alpha_k \,\mathrm{erf}(\gamma_k r)$ in the coordinate space through the Fourier transformation, with $\mathrm{erf}(x)$ the error function. We parametrize this behavior in a simple form

$$\alpha_s(r) = \alpha_{critical} \tanh\left((r/d)^2\right), \tag{5}$$

$$\alpha_{critical} = \frac{g^2}{4\pi} = \frac{g_t^2}{4\pi N_c}, \tag{6}$$

with d the infrared cutoff ($\sim 1/\Lambda_{QCD} \simeq 4GeV^{-1}$). The potential V_G in (3), with $\alpha_s(r)$ specified by (5), is shown in FIG.1.

FIG.1. The chiral angle profile given by (14) and the effective potential $V_G(r)$ as a function of radial distance r in fm.

Inclusion of the second (Skyrme) term in (2) may raise issues of double counting of baryons[1], since the purely pionic part of the Lagrangian 1 can have Skyrmion solutions, with masses of order N_c[2], in addition to the N_c-quark states described above. Here, the nontrivial solution of the Skyrme Lagrangian (2) carries a topological charge[18, 21] B_π known as baryon number, which may violate the baryon number $B = 1$. This is the case if one ignores the nontrivial vacuum effect that may arise from the spectral asymmetry of the quark states. However, as Rho et. al. [22, 23] noted, the quark spectrum is not symmetric about zero energy and therefore that the quark vacuum can carry nonzero baryon number,

$$B_{vac} = -\frac{1}{2} \lim_{t \to +0} \sum_n \mathsf{sgn}(E_n) e^{-t|E_n|}, \tag{7}$$

where the sum is taken over all positive- and negative energy single-particle eigenstates of quark with the level E_n.

While no general proof is available, we argue, by analogy with the proof[24] in chiral bag model, that when applying (1) to a baryon the contribution B_{vac} to baryon number from the quark vacuum polarization (spectrum asymmetry) due to the nontrivial boundary conditions and the contribution B_{Sk} from the Skyrmion conceals exactly, $B_{vac} = -B_{Sk}$, leaving a unity baryon number in total, $B = B_{vac} + B_{Sk} + B_{3q} = B_{3q} = 1$. Here, the baryon numbers carried by pion are defined[18, 23, 21] as

$$B_\pi = \int_{V_\pi} \frac{d^3x}{24\pi^2} \epsilon^{\mu\nu\lambda} tr[U^\dagger \partial_\mu U U^\dagger \partial_\nu U U^\dagger \partial_\lambda U]. \tag{8}$$

where V_π is the region pion field exists. The grounds for the analogy with the chiral bag comes from the observation that the numbers in (7) and (8) are topological in their nature in the sense that they are invariant upon smoothly varying of the solutions to the model (1) insofar as the boundary condition for q and U remain intact. The cancellation identity $B_{vac} = -B_\pi$, which is valid for the chiral bag[24], remains intact as one smoothly varies the solution to (1) to that of the chiral bag, corresponding to varying of the confining potentials S and V_G into that of bag.

---

[1] This has already been discussed in Ref.[16], where a way is shown that binding a second pion can be avoided. In Ref. [14], Weinberg argued that the contribution from quark loops in addition to the tree approximation for purely pionic interactions has to be taken into account at moderate energies of order Λ_{QCD} probed in the structure of Skyrmions, and this contribution may invalidate the argument of baryon number double counting.

3 Hartree wavefunction of quark in ground state baryon

The Hartree picture for a baryon suggests a Hamiltonian being the sum of N_c identical quark Hamiltonians[2],$\mathcal{H}^{Baryon} = N_c\mathcal{H}^q$, and the baryon wavefunction $\Psi(x_1, \cdots, x_N)$ being the product of the single-quark wavefunctions $q(x_i)$(the antisymmetric color part is not included here),

$$\Psi(x_1, \cdots, x_{N_c}) = \prod\nolimits_{i=1}^{N_c} q(x_i), \tag{9}$$

which becomes exact at $N_c \to \infty$ limit[2]. Here, $\mathcal{H}^q$ is the effective Hamiltonian of a single quark in Hartree potential, and is taken, in this work, to be the corresponding Hamiltonian associated with (1).

To determine Ψ, one has to make stationary the variational functional $\langle\Psi|\mathcal{H}^{Baryon} - E|\Psi\rangle$, or equivalently, $\langle\Psi|\mathcal{H}^{Baryon} - N_c\epsilon|\Psi\rangle$ where ϵ is the energy of a single quark in the Hartree potential. If we denote the Hamiltonian associated with (1) by $\mathcal{H}^0 + \mathcal{H}^\chi$, with $\mathcal{H}^0$ the Lagrangian of a single quark in baryon, the Hartree picture, to the leading order of N_c, suggests a Hamiltonian of baryon

$$\mathcal{H}^{Baryon} = \sum\nolimits_{i=1}^{N_c} \mathcal{H}^0(x_i) + \mathcal{H}^\chi, \tag{10}$$

$$\begin{gathered}\mathcal{H}^{(0)}(x_i) = -i\boldsymbol{\alpha}\cdot\boldsymbol{\nabla}_i + \gamma^0(m_q + S(x_i))U_5(x_i) + V_G(x_i),\\ \mathcal{H}^\chi = \tfrac{f_\pi^2}{4}tr(\partial^k U\partial^k U^\dagger) + \tfrac{1}{16e_s^2}tr[(\partial^k U^\dagger\partial^k U)^2 - (\partial^k U^\dagger\partial^l U)^2],\end{gathered}$$

with $S(x)$ and $V_G(x)$ given by (3). Here, $\mathcal{H}^\chi$ is the Hamiltonian associated with Lagrangian(2), x_i is the coordinate of the i-th quark, while the collective chiral field $U = U(x)$ depends only on the coordinate x of the Goldstone boson. Keeping the N_c-dependence of f_π and e_s in mind, one readily sees that $\mathcal{H}^\chi \sim \mathcal{O}(N_c)$, so that $\mathcal{H}^{Baryon} \sim N_c$, as argued by Witten[2].

We consider the two-flavor case of baryons with nontrivial configuration of chiral field of pions. For this, we use the hedgehog ansatz for the chiral field in (10), $U(r) = \exp[iY(r)\boldsymbol{\tau}\cdot\hat{r}]$, where r originated at the mass center of baryons. Writing the quark wavefunction (with the antisymmetric part of color ignored) as $q = \frac{\sqrt{D}}{r}(G(r), -iF(r)\boldsymbol{\sigma}\cdot\hat{r})^t y_{ljm}(\theta\varphi)\chi_f$, with $D \equiv 1/[\int dr(G^2 + F^2)]$, y_{ljm} the Pauli spinor and χ_f the flavor wavefunction, and using (10) and (9), one can rewrite the functional $\langle\Psi|\mathcal{H}^{Baryon} - N_c\epsilon|\Psi\rangle$ in terms of the single quark wavefunction q. The result is

$$H^{Baryon} = N_c[M^0 + M^{Sk}/N_c], \tag{11}$$

where

$$\begin{aligned} M^0 \equiv D^2 \int dr \left\{F\tfrac{dG}{dr} - G\tfrac{dF}{dr} + \tfrac{2\kappa}{r}GF + (m_q+S)\cos Y(G^2-F^2) \right. \\ \left. + V_G(G^2+F^2)\right\}, \\ M^{Sk} = \tfrac{2\pi f_\pi}{e_s}\int dz \left[z^2\left(\tfrac{dY}{dz}\right)^2 + 2\sin^2 Y\cdot\left(1+\left(\tfrac{dY}{dz}\right)^2\right) + \tfrac{\sin^4 Y}{z^2}\right] \end{aligned} \tag{12}$$

with $z \equiv r/L \equiv ef_\pi r$ and $-\kappa$ the eigenvalue of the grand spin operator $K = \gamma^0[\mathbf{\Sigma}\cdot(\mathbf{r}\times\mathbf{p})+1]$ corresponding to the eigenstate y_{ljm}.

The equation of motion of (11) for the S-state($l=0$) is

$$\begin{aligned} \tfrac{dG}{dz} + \tfrac{\kappa}{z}G = [\varepsilon_q + (Lm_q + LS)\cos Y - LV_G]F, \\ -\tfrac{dF}{dz} + \tfrac{\kappa}{z}F = [\varepsilon_q - (Lm_q + LS)\cos Y - LV_G]G, \end{aligned} \tag{13}$$

with $\varepsilon_q = L\epsilon$, $LS = z/(e_s f_\pi a)^2$, $LV_G = f_c\alpha_s/z$, and $a \equiv 1/\sqrt{\sigma_{string}}$.

Before solving (13) one has to know $Y(z)$, which is coupled to (G,F) through the term $\bar{q}U_5 q \sim (G^2-F^2)\cos Y$ in (12). We use adiabatic approximation to determine the static Skyrmion profile first and then solve (13) for (G,F). A good fit of the hedgehog Skyrmion[25] was given by that of the kink-like[26, 27]

$$Y(z) \simeq 4\arctan(e^{-1.002z}), \tag{14}$$

which is obtained by minimizing the energy functional $M^{Sk}[Y(r)]$ in (12) to the value $M^{Sk} = 73.62 f_\pi/e_s$, and does not depend upon the parameters f_π and e_s. This is comparable to the result $M^{Sk} = 73 f_\pi/e_s$ in Ref. [25]. The plot of the profile (14) against $r = z/(e_s f_\pi)$ is presented in FIG.1.

Given the coupling (5) and the profile (14), one can solve the equations (13) numerically in the case $N_c = 3$ for the parameters in Table I. The result for the spinor wavefunction (G,F) is given in FIG.2.

TABLE I. The parameters of the chiral model. The parameters marked by asterisk are inputs from the data, and $\alpha_{critical}= g_t^2/(8\pi)$.

Parameters	This work	CI[20]	ChBM[17]	SK[25]

FIG.2 The spinor wavefunction (G, F) against the radial distance r (fm).

FIG.3. The nonrelativistic wavefunction of the light quark against r (fm).

It is useful to reduce the spinor wavefunction of quark into its nonrelativistic form. It can be given by

$$\phi(\mathbf{x}) = \frac{\sqrt{D}G(r)}{r}[1 + F(r)^2/G(r)^2]^{1/2}, \tag{15}$$

which satisfies the normalization $\int |\phi(r)y_{ljm}|^2 d^3x = 1$, and is plotted in FIG.3.

We note that the isospin symmetry is implicitly assumed here so that the masses of the up and down quarks equal, $m_q = m_{ud}$. The parameters are compared to the corresponding quantities or the counterparts that used in the other calculations. The solution (15) gives a leading order approximation to relativistic quark wavefunction. It will be used to compute the mass correction arising from the strong hyperfine interaction($\sim 1/N_c$) in the perturbative framework in the section 4 and 5.

4 Mass splitting from hyperfine interaction at order $1/N_c$

Being of the order N_c[2], the Hartree interactions in (10) and (11) discussed in the section 2 and 3 is not sufficient to map the baryon mass splitting in the real world($1/N_c = 1/3$) which has to be considered as a subleading correction to the Hartree approximation of baryon. In fact, with the help of the large N_c consistency conditions[4, 28], Jenkins [29] shows that baryon mass splittings are proportional to J^2(J is spin quantum number of baryon) and first allowed at order $1/N_c$. One of striking illustrations for this is the Skyrme model, where the mass splittings, due to rigid rotation of soliton, are proportional to J^2/N_c[25].

Following the non-relativistic quark models[30, 20], we consider the spin-dependent pairwise interaction between quarks in baryon which is inspired by the Breit-Fermi interaction of QED[31], and thereby study the hyperfine mass splitting of baryons. The hyperfine splitting part of the Breit-Fermi interaction inspired by QED reads[30]

$$H_{ij}^{hyp} = \sum_{i<j} \frac{2\alpha_s}{3m_i m_j} \left\{ \frac{8\pi}{3} \delta^3(\mathbf{r}_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j + \frac{1}{r_{ij}^3} \left(3(\mathbf{s}_i \cdot \hat{\mathbf{r}}_{ij})(\mathbf{s}_j \cdot \hat{\mathbf{r}}_{ij}) - \mathbf{s}_i \cdot \mathbf{s}_j\right) \right\}. \tag{16}$$

To the Hamilton (10), which scales like N_c, we add the following two-body hyperfine interactions,

$$\mathcal{H}^{ss} = \frac{1}{N_c - 1} \sum_{i<j=1}^{N_c} V_{ij}^{ss}, \tag{17}$$

with

$$V_{ij}^{ss} = \frac{f_c \alpha_s(r_{ij})}{m_i m_j} \left\{ \frac{8\pi}{3} \delta^3(\mathbf{r}_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j + \frac{1}{r_{ij}^3} \left(3(\mathbf{s}_i \cdot \hat{\mathbf{r}}_{ij})(\mathbf{s}_j \cdot \hat{\mathbf{r}}_{ij}) - \mathbf{s}_i \cdot \mathbf{s}_j\right) \right\} \tag{18}$$

where m_i, $\mathbf{s}_i$ are the mass and spin of the i-th quark in the baryon center-of-momentum frame, and $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$ are the relative coordinate of the quark i and j. From (17) and (18), one can check that $\mathcal{H}^{ss} \sim 1/N_c$ for the low-spin states with the baryon spin $J \ll N_c/2$, if we notice that the sum in (17) (put $m_u \simeq m_d$),

$$\sum_{i<j} \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{m_i m_j} \simeq \frac{1}{2m_u^2} \left[J(J+1) - \frac{3N_c}{4} \right] \tag{19}$$

becomes $\left[j(j+1) - 3N_c\right]/(8m_u^2)$ for $J = j/2 \ll N_c/2$ and $\left[N_c(N_c-1)\right]/(8m_u^2)$ for $J = N_c/2$, which grows like N_c^2 at large N_c. However, we emphasize that the later case does not indicate that the perturbative method fully fails for $J \sim N_c/2$ with $N_c = 3$ because in that situation (19) is $9/(2m_u)^2 \sim 1$.

The factor $1/(N_c - 1)$ in (17) comes from the generalization of the "*1/2*" rule[32, 33] for pairwise interaction of quarks in a baryon to the N_c-body cases. The "*1/2*" rule claims that the pair potential between two quarks in a baryon is half the quark-antiquark potential in a meson. Intuitively, it says that two quarks in a baryon can be seen, when they come closer together, as a localized $\bar{3}$ source which is equivalent to an antiquark as in a meson. Sharing the $\bar{3}$ source by the color charge of each quark, the "1/2" rule follows. For the same reason, $N_c - 1$ quarks in a baryon consists of N_c quarks appear as a $\bar{N}_c$ source which is equivalent to an antiquark, and the factor $1/(N_c - 1)$ in (17) follows when the $\bar{N}_c$ source is shared by each of the $N_c - 1$ quarks in the $\bar{N}_c$ source.

The delta function in (18) is to be smeared[20] by

$$\rho_{ij}(\mathbf{r} - \mathbf{r}') = \frac{\sigma_{ij}^3}{\pi^{3/2}} e^{-\sigma_{ij}^2 (\mathbf{r}-\mathbf{r}')^2}. \tag{20}$$

While σ_{ij} are sensitive to the flavors of quarks for meson, it is not for baryon[20]. Thus, for baryon, one can replace σ_{ij} by a single parameter σ: $\rho_{ij} \to \rho_\sigma \equiv \sigma^3/\pi^{3/2} e^{-\sigma^2(\mathbf{r}-\mathbf{r}')^2}$.

By adding (17) to (11), one has

$$M^{Baryon} = N_c \left[M^0 + \frac{M^{Sk}}{N_c} \right] + M^{ss}, \tag{21}$$

$$M^{ss} = \langle B | \mathcal{H}^{ss} | B \rangle. \tag{22}$$

The expectation value is taken over the nonrelativistic state $|B\rangle$ of baryon because the operator (17), analogous to the Breit-Fermi term of QED, is defined over the subspace which consists of the nonrelativistic wavefunction(denoted as Ψ_B). As a nonrelativistic approximation, Ψ_B can be given by

$$\Psi_B \simeq \prod\nolimits_{i=1}^{N_c} \phi(x_i) \chi_{sf}, \tag{23}$$

with χ_{sf} the $SU(6)$ spin-flavor wavefunction of baryon. Given Ψ_B with the one-body orbital wavefunction ϕ solved form (13), one has

$$M^{ss} = \langle \Psi_B | \mathcal{H}^{ss} | \Psi_B \rangle. \tag{24}$$

For the S-wave of baryons, the second term in (18) vanishes. Before computing (24) we smear the delta function in (18), considering simultaneously the r-dependence of $\alpha_s(r)$ in (5), according to the Breit-Fermi-like interaction[20], $\frac{7}{3m_im_j}\mathbf{s}_i\cdot\mathbf{s}_j\boldsymbol{\nabla}^2V_{int}$. This can be done by simply rewriting $\alpha_s\delta(\mathbf{r}_{ij})$ in the form of the Laplace expression $\boldsymbol{\nabla}^2\left(-\alpha_s(r_{ij})/4\pi r_{ij}\right)$ at first and then smear $\delta(\mathbf{r}_{ij})$ with ρ_σ. Using (18) one has for the mass splitting (24)

$$\begin{aligned} M^{ss} &= \sum_{i<j}\frac{8\pi f_c\alpha_{critical}}{3(N_c-1)m_im_j}\langle\Psi_B|\alpha(r_{ij})\delta^3(\mathbf{r}_{ij})\mathbf{s}_i\cdot\mathbf{s}_j|\Psi_B\rangle, \\ &= \sum_{i<j}A_{ij}\frac{\mathbf{s}_i\cdot\mathbf{s}_j}{m_im_j}, \end{aligned} \tag{25}$$

where $\alpha_s(r)\equiv\alpha_{critical}\cdot\alpha(r)$ is given by (5), with

$$\alpha(r)\equiv\tanh((r/d)^2), \tag{26}$$

and

$$A_{ij}\equiv\frac{g_t^2(1+1/N_c)}{3N_c}\left\langle ij\left|\boldsymbol{\nabla}^2\left(\frac{\alpha(r_{ij})}{4\pi r_{ij}}\right)\right|ij\right\rangle. \tag{27}$$

Here, $|ij\rangle\equiv|\phi(x_i)y_{ljm}^{(i)}\rangle|\phi(x_j)y_{ljm}^{(j)}\rangle$ with $|\phi(x_i)y_{ljm}^{(i)}\rangle$ the spatial and spin wavefunction of the i-th quark, and the relations (23), (6) and $f_c\alpha_{critical}=g_t^2/(8\pi)(1-1/N_c^2)$ are used. Noticing the mathematical identity

$$\boldsymbol{\nabla}^2\left(\frac{\alpha(r)}{4\pi r}\right)=\alpha(r)\delta^3(r)-\frac{d^2\alpha(r)/dr^2}{4\pi r}, \tag{28}$$

and making replacement $\delta^3(r)\to\rho_\sigma(r)$ subsequently, one has the smeared results for (27),

$$A_{ij}=\frac{g_t^2(1+1/N_c)}{6N_c}[A_{ij}^{(1)}-A_{ij}^{(2)}]. \tag{29}$$

where (see appendix A).

$$A_{ij}^{(1)} = \int\int dr_1r_1^2dr_2r_2^2|\phi_i(r_1)|^2|\phi_j(r_2)|^2\frac{\sigma^3e^{-\sigma^2(r_1^2+r_2^2)}}{\pi^{3/2}}U_1(r_1,r_2), \tag{30}$$

$$A_{ij}^{(2)} = \int\int dr_1r_1^2dr_2r_2^2|\phi_i(r_1)|^2|\phi_j(r_2)|^2\frac{1}{4\pi}U_2(r_1,r_2), \tag{31}$$

and

$$\begin{aligned} U_1(r_1,r_2) &\equiv \int_{-1}^{+1}du e^{2r_1r_2\sigma^2u}\alpha\left((r_1^2+r_2^2-2r_1r_2u)/d^2\right), \\ U_2(r_1,r_2) &\equiv \int_{-1}^{+1}du\frac{\alpha''\left((r_1^2+r_2^2-2r_1r_2u)/d^2\right)}{\sqrt{r_1^2+r_2^2-2r_1r_2u}}, \end{aligned} \tag{32}$$

Here, $\alpha(r)$ is given by (26) and $\alpha''=d^2\alpha(r)/dr^2$ its second-order derivative, and ϕ_i stands for the solution (15), solved with the mass $m_i(i=u,d)$.

Ignoring the isospin breaking, one can replace $A_{ij}^{(m)}$ $(m = 1, 2)$ by a single parameter $A_{ij}^{(m)} \simeq A^{(m)}$, and thereby finds

$$A = \frac{g_t^2(1 + 1/N_c)}{6N_c}[A^{(1)} - A^{(2)}]. \tag{33}$$

with $A_{ij}^{(1,2)}$ given by (30) and (31). From the equations (26), (30), (31) and (32), one can easily see that $A \sim 1/N_c$ at large N_c.

Putting (25) into (11), we obtain

$$M^{Baryon} = N_c M^0 + M^{Sk} + A \sum_{i<j=1}^{N_c} \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{m_i m_j}, \tag{34}$$

with M^0, M^{Sk} given by (12) and A by (33). Notice that (34) has the form of expansion $M^{Baryon} = a_0 N_c + a_1/N_c$ since $M^{Sk} \sim N_c$ and $A \sim 1/N_c$. This is exactly what the large-N_c QCD predicts[29] for the $SU(3)_F$ symmetry limit.

5 Extension to three flavor case

In order to determine the 't Hooft coupling, we need more informations about the baryons than the two-flavor case considered in preceding sections to fix the parameters in (1). For this purpose, one has to extend the formula (34) into the three flavor case which includes the effects of the flavor $SU(3)$ breaking. One convenient way to do this is to attribute the $SU(3)_F$ breaking simply, as the naive quark model, to the mass differences of the quarks between strange and non-strange flavors, including the resulted differences of the single-particle mean-field energy $M^{(i)}(i = u, d, s)$ for quarks, defined by (12).

We introduce the strange quark mass m_s(bigger than m_{ud}) so that the mass difference $m_s - m_{ud}$ breaks the flavor $SU(3)$ breaking explicitly. Instead of computing the strange quark mass $M^{(s)}$ directly using the bound state approach to strangeness[34], for instance, one can determine it by simply fitting the data of the mass difference between Λ and nucleon. We then generalize the mass formula (34) into

$$M^{Baryon} = \sum_{i=1}^{N_c} M^{(i)} + M^{Sk} + A \sum_{i<j=1}^{N_c} \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{m_i m_j}, \tag{35}$$

where A and M^{Sk} are taken to be same for three flavors $(i = u, d, s)$ including the strange quark, $M^{(u)} = M^{(u,d)} \equiv M^0$ is defined in (12). By applying (35) to $\Lambda = uds$ and nucleon and eliminating the mass splitting, one has $M^{(s)} = M^{(u)} + \delta M_{\Lambda\text{-}N}$, which gives (with the experimental data $\delta M_{\Lambda\text{-}N} = 175MeV$)

$$M^{(s)} \simeq M^{(u)} + 175MeV. \tag{36}$$

The relation (35) is to be compared with the ground-state mass formula of the nonrelativistic quark model[30, 35]

$$M = \sum_{i=1}^{3} m_i + A' \sum_{i<j=1}^{3} \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{m_i m_j}, \tag{37}$$

with $A' = (2m_{ud})^2 50MeV$, and that of the Skyrme model[36]

$$M = M^{soliton} + \left(\frac{1}{2I_1} - \frac{1}{2I_2} \right) \mathbf{J}^2 + \frac{1}{2I_2} \left[C^{p,q} - \frac{N_c^2}{12} \right], \tag{38}$$

with $C^{p,q}$ the Casimir operator and $I_{1,2} \sim N_c$ the moments of inertia of soliton($I_1 = 53/(f_\pi e_s^3)$ and $I_2 = 19.5/(f_\pi e_s^3)$, approximately).

We will show that (35) and (37) can be understood in the context of large-N_c QCD, which claims [4, 28] for the $SU(3)_F$ breaking case,

$$M = a_0 N_c + a_1 \frac{\mathbf{J}^2}{N_c} + b_1 \epsilon_F T^8 + \epsilon_F b_2 \frac{J^i G^{i8}}{N_c} + \cdots. \tag{39}$$

Here, ϵ_F is the $SU(3)_F$ breaking, $T^8 = (N_c - N_s)/\sqrt{12}$, $G^{i8} = (J^i - 3J_s^i)/\sqrt{12}$, J^i and J_s^i are spins of the baryon and strange quark, respectively, and N_s the number of the strange quark, This can be seen if we notice the relation (19) for two flavor case and its generalization of the three-flavor case.

The three-flavor generalization of the relation (19) can be given, for the strangeness$= -N_s$ baryons, by

$$\begin{aligned} \textstyle\sum_{i<j=1}^{N_c} \frac{\mathbf{s}_i \cdot \mathbf{s}_j}{m_i m_j} = \left(\frac{m_s}{m_q} - 1 \right) \textstyle\sum_{k<k'=1}^{N_c - N_s} \frac{\mathbf{s}_k \cdot \mathbf{s}_{k'}}{m_q m_s} + \left(1 - \frac{m_s}{m_q} \right) \textstyle\sum_{I<I'=1}^{N_s} \frac{\mathbf{s}_I \cdot \mathbf{s}_{I'}}{m_s^2} \\ + \frac{1}{m_q m_s} \left[\frac{J(J+1)}{2} - \frac{3N_c}{8} \right], \end{aligned}$$

then, when adding of the extra contribution $N_s(M^{(s)} - M^{(u)})$ to the order-N_c mass $N_c M^0$ stemming from the strange-up energy difference $\delta M \equiv M^{(s)} - M^{(u)}$, one finds for the baryon mass formula (35) with three flavors

$$\begin{aligned} M^{Baryon} &= N_c M^0 + \left[M^{Sk} - \frac{3(AN_c)}{8 m_s m_q} \right] + A \frac{J(J+1)}{2 m_q m_s} + N_s \delta M \\ &\quad + \left(\frac{m_s}{m_q} - 1 \right) A \left[\sum_{k<k'=1}^{N_c - N_s} \frac{\mathbf{s}_k \cdot \mathbf{s}_{k'}}{m_q m_s} - \sum_{I<I'=1}^{N_s} \frac{\mathbf{s}_I \cdot \mathbf{s}_{I'}}{m_s^2} \right] \end{aligned} \tag{40}$$

where the small indices k and k' refer to the non-strange quarks(u and d), and the capital indices to the strange quark, $m_q \equiv m_{ud}$, $\delta M \propto \epsilon_F \propto \left(\frac{m_s}{m_q} - 1\right)$.

From (40), we see that the third term scales like $1/N_c$ the fourth like ϵ_F, and the last scales as ϵ_F/N_c, corresponding to the second, the third and the fourth terms in (39), respectively. We note here that δM is of order $\mathcal{O}(1)$ and $A \sim \mathcal{O}(1/N_c)$. The individual spin product $\mathbf{s}_i \cdot \mathbf{s}_j$ $(i, j = u, d, s)$ in (35) or (37) is 3/4 if the spins of the quark(i and j) are parallel and $-3/4$ they are anti-parallel.

Knowing the wavefunction (15) solved in the section 3 and the resulted energies $M^{(u)} = M^0$ and M^{Sk} given by (12), and using (36) and (33), one can map the masses of the octet and decuplet baryons using (35). Our results for the optimal fit of g_t and A in (33) are

$$g_t = 1.571,\ A = 0.000243,$$

with the corresponding masses (35) calculated for the parameters in Table I listed in the Table II.

TABLE II. The calculated baryon masses are compared with experiment (in MeV/c^2) when $N_c = 3$. The values for 't Hooft coupling and mass splitting coefficients in our work are $g_t = 1.571$ and $A = 0.000243$, respectively.

6 Summary and concluding remark

We studied the 't Hooft coupling and the baryon masses hyperfine splittings of the ground state baryons in a chiral quark model inspired by the large-N_c QCD. The Hartree picture of baryon at large N_c is used to map the masses of octet and decuplet baryons in the ground states. The 't Hooft coupling g_t that reproduces data of masses is found to be about 1.57. We believe that this gives an indication that in Weinberg's effective field theory, the 't Hooft coupling g_t becomes small in the sense that $g_t^2/4\pi N_c \ll 1$ at moderate energies.

The fact that the quantum numbers and the group theoretic structure of baryons in the Skyrme model is identical to that of the naive quark model at large N_c[39] implies some yet unknown connection between the two. We hope that the large-N_c chiral model considered in this paper will enhance this connection, as indicated by (35), (37) and (38), in the sense that both fit well into the large N formula (39).

Acknoledgements

Appendix A

We write the smeared matrix element $\langle ij\,|\alpha(r_{ij})\rho_\sigma(r_{ij})|\,ij\rangle$ in (27) as

$$\int\int d^3r_1 d^3r_2|\phi_i(r_1)|^2|\phi_j(r_2)|^2|y^{(i)}_{ljm}y^{(j)}_{ljm}|^2\alpha(r_{ij})\rho_\sigma(r_{ij})$$
$$=\frac{(2\pi)^2}{(4\pi)^2}\int_0^\pi d\theta_1\sin(\theta_1)d\theta_2\sin(\theta_2)\int dr_1dr_2r_1^2r_2^2|\phi_i(r_1)|^2|\phi_j(r_2)|^2$$
$$\times\,\alpha(|\mathbf{r}_1-\mathbf{r}_2|)\rho_\sigma(|\mathbf{r}_1-\mathbf{r}_2|),$$

where $r_{ij}^2=|\mathbf{r}_1-\mathbf{r}_2|^2=r_1^2+r_2^2-2r_1r_2\cos(\theta_2-\theta_1)$ when one choose the frame (r_1,θ_1,φ_1) and (r_1,θ_1,φ_1) so that the three vector $\mathbf{r}_1,\mathbf{r}_2,\mathbf{z}$ in the same plane. Make a change of variables from (r_1,θ_1,φ_1) and (r_1,θ_1,φ_1) to (r_1,θ_1,φ_1) and $(r_1,\theta_2-\theta_1,\varphi_2)$, and performing the integration, one gets (30), with $U_1(r_1,r_2)$ given by (32). Similarly, one can get (31) for $\langle ij\,|\alpha(r_{ij})\rho_\sigma(r_{ij})|\,ij\rangle$. Here, we give the alternative expressions for (30), (31) and (32), with the integration over the dimensionless variable $z=r/L$, which are convenient for the numerical computation of mass splittings.

$$A_{ij}^{(1)}=\frac{(DL)^2\sigma^3}{\pi^{3/2}}\int\int dz_1dz_2|\phi_i(z_1)|^2|\phi_j(z_2)|^2e^{-L^2\sigma^2(z_1^2+z_2^2)}U_1(z_1,z_2)$$
$$A_{ij}^{(2)}=\frac{(DL)^2}{4\pi}\int\int dz_1dz_2|\phi_i(z_1)|^2|\phi_j(z_2)|^2U_2(z_1,z_2)$$

$$U_1(z_1,z_2)=\int_{-1}^{+1}due^{2z_1z_2L^2\sigma^2u}\tanh\left((z_1^2+z_2^2-2z_1z_2u)\left(\frac{L}{d}\right)^2\right),$$
$$U_2(z_1,z_2)=\frac{1}{L^3}\int_{-1}^{+1}du\frac{\tanh''\left((z_1^2+z_2^2-2z_1z_2u)\left(\frac{L}{d}\right)^2\right)}{\sqrt{z_1^2+z_2^2-2z_1z_2u}}.$$
